Remove server.js.

Why does

sudo ./install.sh hotletter.neolamia.com

have hotletter.neolamia.com in it? That's for my installation.

1. `server.js` Removed

- Deleted `server.js` from `/addr.bar/tricurse/server`.
- Removed all documentation sections and references to `server.js` from README.md.

---

2. Why `hotletter.neolamia.com` was in the Command

- **Not in the script logic**: `hotletter.neolamia.com` was **never hardcoded in install.sh**. The script takes whatever website name is passed via `$1` (e.g. `sudo ./install.sh <domain>`) or prompts interactively if left blank.
- **It was used as the example in the README**: In the previous documentation draft, I used your target domain (`hotletter.neolamia.com`) in the code examples to illustrate your setup. You are completely right: for a public repository (`github.com/addressbar-net/server`), public documentation should use generic placeholders rather than your personal domain.
- **Updated to generic placeholders**: All examples in README.md and PROCESS_GUIDE.md now use standard placeholders:

```
sudo ./install.sh example.com
# or
sudo ./install.sh <your-domain.com>
```

---

3. Git Status

The removal of `server.js` and the generalized documentation edits have been committed to the repository's `main` branch:

```
commit 6cea878: Remove server.js and generalize domain examples in documentation
```

The working tree in `/addr.bar/tricurse/server` is clean and ready to `git push`.
